Kaleido

EXECUTIVE OVERVIEW

Business capabilities. Built for people and AI.

Typed. Discoverable. Stateful.

A shared contract for business information and actions, with an implemented MCP interface for AI agents.

AI-native interface. Business-owned decisions.

The idea needed a working example.

THE COMMUNICATION GAP

Explaining the step concept was not making the real scenarios click.

After several years of explaining the idea, the missing piece was something people could see working.

MAKE THE ACTION VISIBLE

Show what a step needs and what it does.

MAKE THE BEHAVIOR VISIBLE

Show what is required, available, or waiting.

MAKE THE REUSE VISIBLE

Run the same model through different consumers.

Kaleido turns an abstract step concept into an executable model people can understand.

Origin story: founder account, paraphrased; technical framing from the step model.

A step is a business action—not a screen.

Select a provider. Capture answers. Submit a request. Each action runs against the current process state.

INPUT + CONTEXT

Provided values
Process state

ONE BUSINESS ACTION

Declared inputs and rules
Business-owned handler
Recorded outcome

RESULT + NEXT

What happened
How to continue

REQUIRED

A particular step must happen next.

AVAILABLE

The caller chooses among allowed steps.

AWAITING INFORMATION

Specific questions need answers.

The channel presents the action. The process contract describes how it may proceed.

Conceptual view of the Process contract; the examples are not a fixed PriorAuth sequence.

Do not create another integration path for AI.

Make business capabilities understandable once—then reuse that understanding across every consumer.

SEPARATE PATHS

Workflow	own adapter + rules
Digital channels	own adapter + rules
AI agents	own adapter + rules

More copies of integration logic.
More places for behavior to drift.

ONE SHARED CONTRACT

Discover the capability.
Understand its inputs.
Read state and next steps.

AI uses the business contract—
not a second definition of the business.

The strategic value: AI access and cross-channel reuse reinforce the same investment.

Architecture rationale and intended value; no quantified savings or live integration result is asserted.

Three building blocks. One AI-native interface.

Business Information, Business Actions, and the Capability Catalog remain the foundation.

QUERYABLE

Business Information

What does the business know?

- Typed sources and views
- Published fields and constraints
- Search, filter, sort, and page

PROCESS

Business Actions

What can the business do?

- Named steps and typed inputs
- Dependencies and availability
- Process state and next guidance

REGISTRY

Capability Catalog

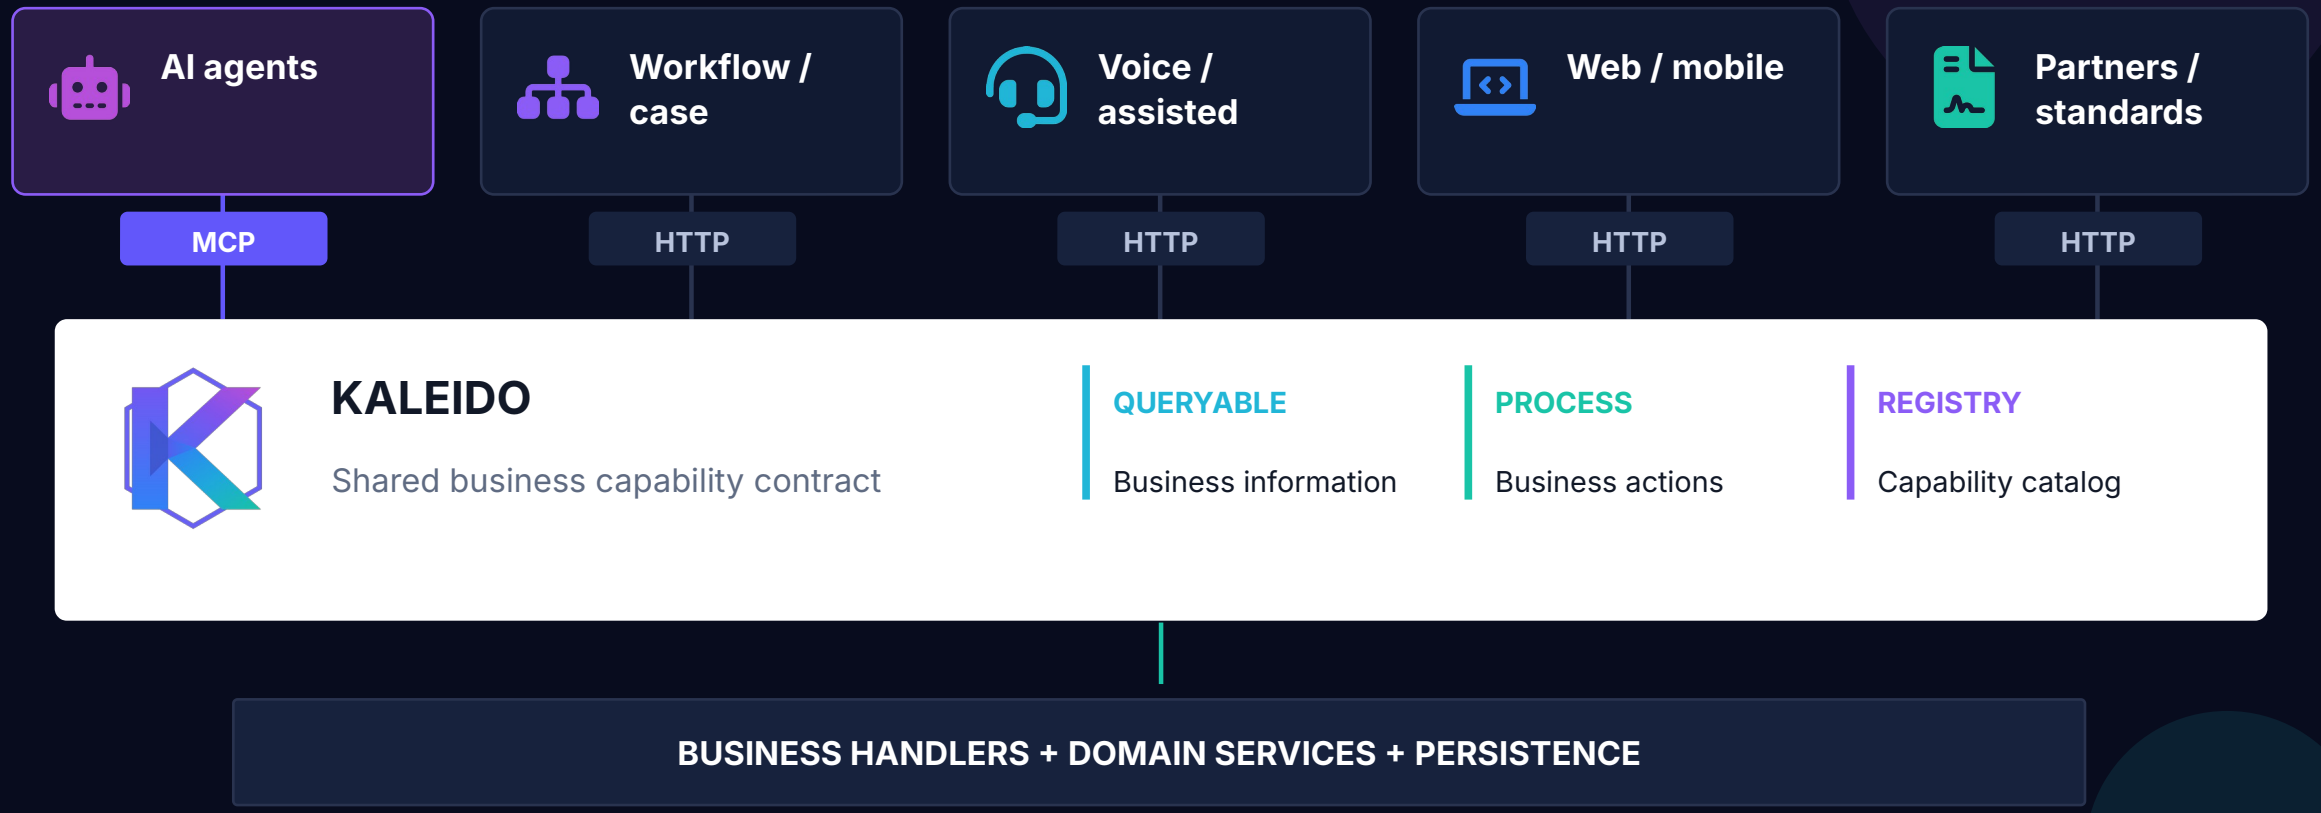

How does a consumer find it?

- Capability names and metadata
- Advertised query / execution routes
- Caller-filtered discovery

MCP exposes this same model as AI tools—not a parallel business implementation.

One model for human and AI consumers.

AI uses MCP; applications use HTTP. Both reach the same capability contracts and business implementations.

The AI model stays outside Kaleido. Business decisions stay in the application.

Illustrative consumer categories. These are not claims of bundled connectors or vendor certifications.

IMPLEMENTED MCP SURFACE

AI can discover, act, ask, and continue.

The agent reads a machine-readable business contract instead of inventing its own process model.

01 DISCOVER

Read the tool catalog

Names, descriptions, schemas, and constraints.

02 LOOK UP

Find real business data

Search first; guide the user to a matching record.

03 ACT

Invoke a declared step

Typed arguments enter the Process runtime.

04 ASK

Collect missing answers

Information requests; forms when supported.

05 CONTINUE

Read state and next

Required steps, available choices, and handoffs.

Human choices and business rules remain authoritative. Tool guidance is not authorization.

Implemented source-level capabilities. Form behavior depends on the MCP client; release validation remains open.

From a conversation to a real business action.

The user chooses and supplies facts. The agent navigates tools. The service checks the business meaning.

PERSON + AI INTERACTION	BUSINESS CONTRACT
Find the right record Search; show matching records. The user selects the intended one.	**Queryable + lookup metadata** Related IDs come from one result. The step handler checks the relationship.
Collect the missing information Ask the service's questions. The user confirms or corrects answers.	**Information request** Kaleido checks the answer structure. The business handler checks its meaning.
Review before submission Present the review and attestation. Continue only with the supplied answer.	**Submission step** The sample checks attestation. Submission is not an approval decision.

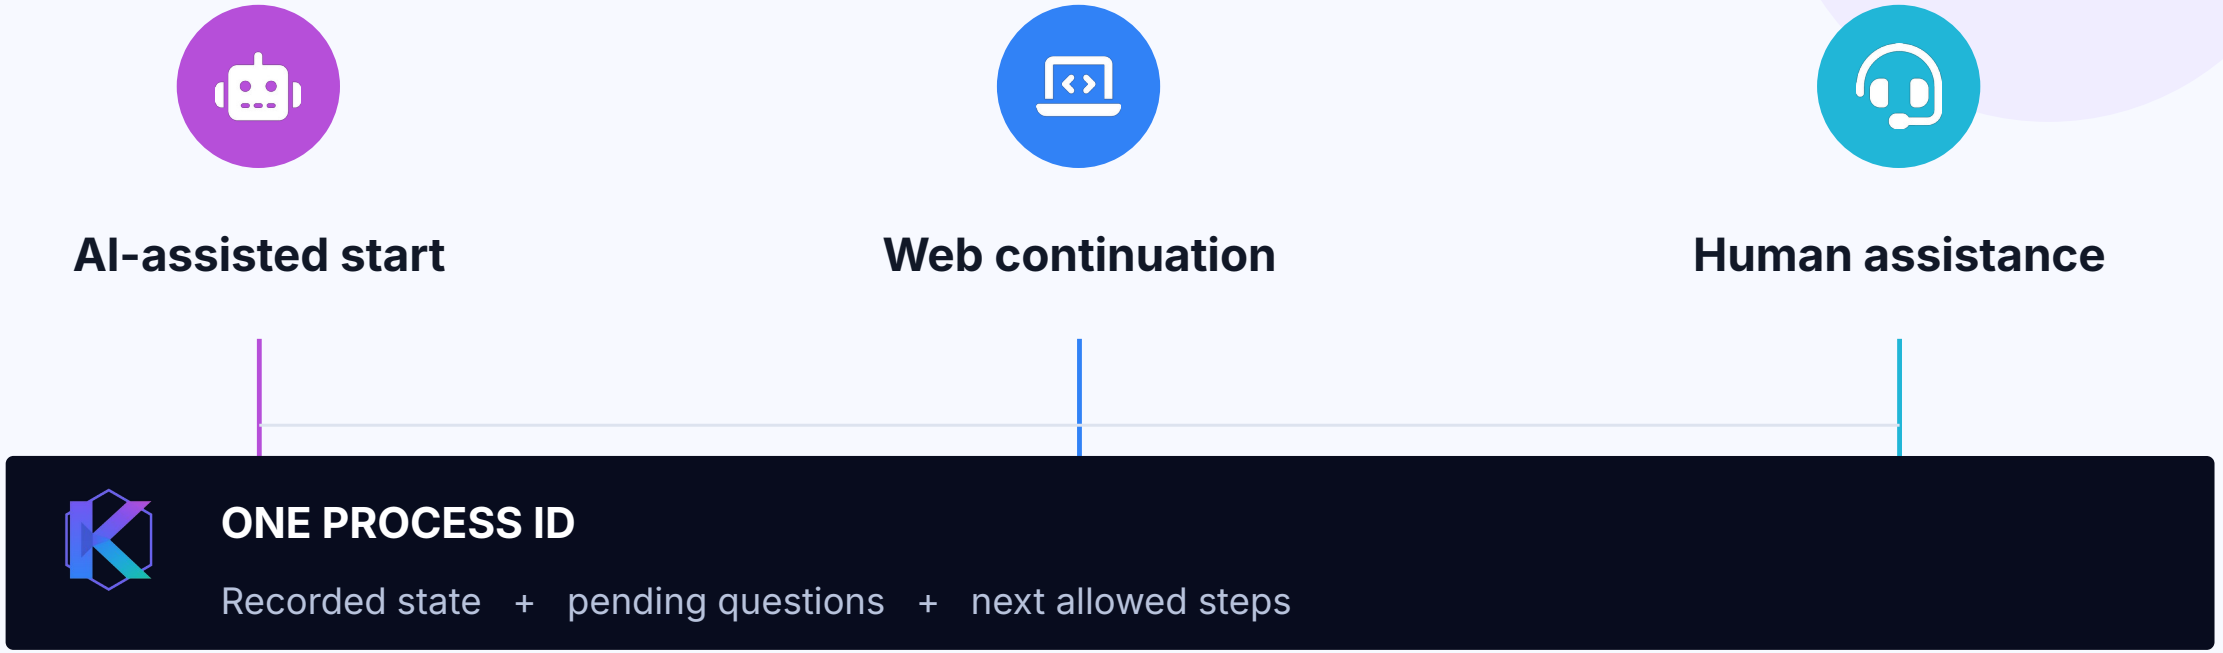

The interaction changes. The business action and its validation do not.

Illustrative interaction based on the PriorAuth sample and MCP contracts; not a recording of a live agent run.

CONTINUITY ACROSS CONSUMERS

The process should outlive the conversation.

A conversation is an interface. The process has its own identity, recorded state, and continuation contract.

The next consumer reloads the process state—not just the previous chat history.

Supported architectural pattern, not proof of a live handoff. Durable storage, identity, and access control are deployment responsibilities.

AI strengthens the platforms already in place.

Keep orchestration, channels, and standards at their boundaries. Reuse the business capabilities underneath.

Workflow & case

Pega and similar platforms

Keep assignments, SLAs, and human work in the workflow platform. Call shared information and actions.

Coordinate work; reuse capabilities.

Voice & assisted

IVR and contact center

Use the same inputs, validation, and process identity across self-service and assisted interactions.

Change channels; retain the model.

Standards & partners

Da Vinci and other boundaries

Map external exchange into stable internal information and action contracts rather than duplicating them.

Adapt the boundary; share the business.

AI is a first-class consumer of that same foundation—not a reason to rebuild it.

Examples of intended integration fit from the original deck; no native Pega connector or Da Vinci conformance claim.

AI-native does not mean unbounded.

Use the model for interaction. Keep authorization, business meaning, and execution guarantees explicit.

IMPLEMENTED MECHANISMS

Discoverable contracts

Tool schemas and caller-filtered catalog.

Process constraints

Input structure, step rules, and state.

Guided interaction

Lookups, information requests, and next steps.

HOST + BUSINESS RESPONSIBILITIES

Who may act

Identity, destination credentials, case access.

What the action means

Domain validation and any required approvals.

What is safe to promise

Retry, completion, privacy, and consent tests.

A prompt or tool hint is guidance—not proof of permission, consent, or exactly-once execution.

Preview scope: MCP credential delegation, retry/completion behavior, and real-client consent flows still require validation.

EXECUTIVE TAKEAWAY

Make the business understandable. Make it usable by AI.

> **Kaleido makes the step concept tangible—and exposes the same business model to AI, applications, and people.**

01

Make the idea visible

Reusable steps with explicit inputs, outcomes, and ways to continue.

02

Make AI a first-class user

An implemented MCP interface over the shared capability contract.

03

Keep the business in charge

Domain logic and authority stay with the business and its host.

Define once. Discover. Act. Continue.
